# Collins Helium Liquefaction Cycle 

Anish Jha<br>Department of Chemical Engineering, Birsa Institute of Technology, Sindri

## Background \& Description:

The Collins cycle also known as modified Claude cycle is mainly used for helium liquefaction. This liquefier consists of five or six heat exchangers and two reciprocating expander. Collins cycle uses a joule Thomson valve or a turboexpander for cooling down the compressed gas by throttling its flow which results in rapid expansion.

The below mentioned flowsheet is of liquefaction of helium using the Collins cycle with a turbo expander in place of Joule Thompson valve.

Helium gas enter the cycle at $-190^{\circ} \mathrm{C}$ and 1 bar with a molar flow rate of $1000 \mathrm{kmol} / \mathrm{h}$. the feed and the recycled product coming all the way through the exchanger mixes and enters in a compressor which increases the pressure to 15 bar. Then the compressed gas is cooled by using various coolers and five different heat exchangers to get liquified helium as shown in fig 1. After getting cooled the compressed gas is to be passed through a Joule Thompson valve so instead of the valve I have used a turbo expander and a cooler to decrease the pressure to 1 bar and temperature $-269^{\circ} \mathrm{C}$ (boiling point of helium). Hence helium is obtained in liquid state at $-269^{\circ} \mathrm{C} .50 \%$ of the product is collected and rest $50 \%$ is heated and sent as a recycle in the Collins cycle.

The liquified helium obtained is at 1 bar and $-269^{\circ} \mathrm{C}$ with molar flow rate of $950.5 \mathrm{kmol} / \mathrm{hr}$.
